

Hadoop Cluster Setup

This is what our environment should look like

Requirements

- Ubuntu Server 18.04, download from: [here](#)
- Install SSH during installation time or after (worst case)
- 5 Virtual Machines, or at least 3 of them. Details could be found in table below.

System	Hostname	IP Address	Role
VM#1	nnode.yourname.local	172.16.150.10	Name Node
VM#2	dnode1.yourname.local	172.16.150.11	Data Node
VM#3	dnode2.yourname.local	172.16.150.12	Data Node
VM#4	dnode3.yourname.local	172.16.150.13	Data Node
VM#5	dnode4.yourname.local	172.16.150.14	Data Node

The Setup

On your main Ubuntu system do the following:

1. Install first and name it “**ubuntu-18.04-BASE**”.
2. **REMINDER:** Install SSH during installation time or after (worst case)
3. Login and update it:

```
$ sudo apt update
```

```
$ sudo apt upgrade
```

4. Install Java OpenJDK 8

```
$ sudo add-apt-repository ppa:openjdk-r/ppa
```

```
$ sudo apt-get update
```

```
$ sudo apt-get install openjdk-8-jdk
```

Verify that it is working:

```
$ java -version
```

```
user1@node:~$ java -version
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.18.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

5. Create a directory for downloading and using for temp stuff.

```
$ mkdir files
```

Now download hadoop inside the new directory

```
$ cd files
```

```
$ wget -c
```

```
http://apache.cbox.biz/hadoop/common/hadoop-3.1.2/hadoop-3.1.2.tar.gz
```

Extract the files:

```
$ tar xvfz hadoop-3.1.2.tar.gz
```

6. Create a Virtual Network using the VMWare Network Editor

7. Configure the IP Address of the BASE

```
$ vim /etc/cloud/cloud.cfg
```

```
# This file is generated from information provided by
# the datasource. Changes to it will not persist across an instance.
# To disable cloud-init's network configuration capabilities, write a file
# /etc/cloud/cloud.cfg.d/99-disable-network-config.cfg with the following:
# network: {config: disabled}
network:
  ethernets:
    ens33:
      addresses: [172.16.150.10/24]
      gateway4: 172.16.150.1
      nameservers:
        addresses: [172.16.150.1]
      dhcp4: no
      optional: true
  version: 2
```

Then apply your settings:

```
$ sudo netplan apply
```

Verify your results:

```
$ ifconfig
```

If you want to speed things up, you might want to check check Note (1) in cyan below.

8. Power off the system and move on to making copies
9. Now switch the network interface of your BASE from **NAT** → **Custom** and choose **vmnet2** (assuming you created vmnet2, otherwise, adjust it to something else).

Network Connection

Bridged: Connected directly to the physical network
 Replicate physical network connection state

NAT: Used to share the host's IP address

Host-only: A private network shared with the host

Custom: Specific virtual network

Creating Clones

10. Within VMWare, go to **Manage** → **Clone**
11. Then choose to create a link clone, repeat the process (4 more times). Name them as following:
 - a. Ubuntu-18.04-NameNode
 - b. Ubuntu-18.04-DataNode1
 - c. Ubuntu-18.04-DataNode2
 - d. Ubuntu-18.04-DataNode3
 - e. Ubuntu-18.04-DataNode4
12. Start the first one (NameNode) and change the IP Address and hostname. It should be as seen in table #1.

```
$ sudo hostnamectl set-hostname nnode.ali.local --static
```

Then edit the `/etc/cloud/cloud.cfg` file in order to preserve the hostname across reboots and change “`preserve_hostname`” from **false** to **true** as seen below.

```
user1@nnode:~$ grep preserve /etc/cloud/cloud.cfg
preserve_hostname: true
```

Reboot your system to double check.

Note (1): the reason why we are adding the hostnames to the hosts file of each system is we do not have a DNS Server, if you do, then no need for this step. If you did this step when installing BASE, then you will not need to repeat it.

Example of Name Node: **nnode.ali.local**

```
user1@nnode:~$ hostname
nnode.ali.local
user1@nnode:~$ ifconfig
ens33: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
        inet 172.16.150.10 netmask 255.255.255.0 broadcast 172.16.150.255
```

Data Node1: **dnode1.ali.local**

```
user1@dnode1:~$ hostname
dnode1.ali.local
user1@dnode1:~$ ifconfig
ens33: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
        inet 172.16.150.11 netmask 255.255.255.0 broadcast 172.16.150.255
```

Data Node2: **dnode2.ali.local**

```
user1@dnode2:~$ hostname
dnode2.ali.local
user1@dnode2:~$ ifconfig
ens33: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
        inet 172.16.150.12 netmask 255.255.255.0 broadcast 172.16.150.255
```

/etc/hosts file

```
127.0.0.1    localhost.localdomain localhost
::1         localhost6.localdomain6 localhost6

172.16.150.10 nnode.ali.local    nnode
172.16.150.11 dnode1.ali.local  dnode1
172.16.150.12 dnode2.ali.local  dnode2
172.16.150.13 dnode3.ali.local  dnode3
172.16.150.14 dnode4.ali.local  dnode4
```

13. Check that all devices can **ping** each other as seen in one example below:

```
user1@dnode1:~$ ping nnode -c1
PING nnode.ali.local (172.16.150.10) 56(84) bytes of data.
64 bytes from nnode.ali.local (172.16.150.10): icmp_seq=1 ttl=64 time=0.251 ms

--- nnode.ali.local ping statistics ---
1 packets transmitted, 1 received, 0% packet loss, time 0ms
rtt min/avg/max/mdev = 0.251/0.251/0.251/0.000 ms
user1@dnode1:~$ ping dnode2.ali.local -c1
PING dnode2.ali.local (172.16.150.12) 56(84) bytes of data.
64 bytes from dnode2.ali.local (172.16.150.12): icmp_seq=1 ttl=64 time=0.522 ms

--- dnode2.ali.local ping statistics ---
1 packets transmitted, 1 received, 0% packet loss, time 0ms
rtt min/avg/max/mdev = 0.522/0.522/0.522/0.000 ms
```

Passwordless Authentication using SSH Keys

Time to setup our boxes to connect to each other using a passwordless authentication method, which is achieved using SSH keys.

14. On the name node use the **ssh-keygen** to create the keys as seen below.

```
user1@nnode:~$ ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/home/user1/.ssh/id_rsa):
Created directory '/home/user1/.ssh'.
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/user1/.ssh/id_rsa.
Your public key has been saved in /home/user1/.ssh/id_rsa.pub.
The key fingerprint is:
SHA256:ScmY9k6nyNYttNBpq93AxJDz3Dc04ZcANyyLeHIIPz0 user1@nnode.ali.local
The key's randomart image is:
+---[RSA 2048]---+
|  ..  ..0 |
| .o . =.+.. |
| ..EoB.+oo |
|  +.+X.= o . |
|   +. S = = |
|   . @ * = . |
|   + X . . |
|   . o + |
|   . . . |
+-----[SHA256]-----+
user1@nnode:~$
```

Repeat the process on all of your systems.

15. Now copy the file over to all of the systems, including the name node itself using the **ssh-copy-id** command.

```
user1@nnode:~$ ssh-copy-id user1@dnnode1.ali.local
/usr/bin/ssh-copy-id: INFO: Source of key(s) to be installed: "/home/user1/.ssh/id_rsa.pub"
The authenticity of host 'dnnode1.ali.local (172.16.150.11)' can't be established.
ECDSA key fingerprint is SHA256:EME3m+DVN7+kbtbLuwZ4sLly2KTCFQxyMJzTum+vAwU.
Are you sure you want to continue connecting (yes/no)? yes
/usr/bin/ssh-copy-id: INFO: attempting to log in with the new key(s), to filter out any that are already installed
/usr/bin/ssh-copy-id: INFO: 1 key(s) remain to be installed -- if you are prompted now it is to install the new keys
user1@dnnode1.ali.local's password:

Number of key(s) added: 1

Now try logging into the machine, with: "ssh 'user1@dnnode1.ali.local'"
and check to make sure that only the key(s) you wanted were added.

user1@nnode:~$
```

16. To test that you are able to login without password and using key based authentication, try to ssh into the system you just copied the key to. It is very important for the rest of the work to be successful that your namenode is able to ssh into the datanodes without a password. An example could be seen below.

```
user1@nnode:~$ ssh user1@dnnode1.ali.local
Welcome to Ubuntu 18.04.2 LTS (GNU/Linux 4.15.0-47-generic x86_64)

user1@node:~$ █
```

17. Move the extracted copy of hadoop from your files directory to the main home directory. We will be using this path for hadoop on any system required:

`/home/user1/hadoop`

18. Open your `.bashrc` file and add Hadoop to the running path, as seen in the example below. If you do not prefer “vim” use “nano”.

`$ vim .bashrc`

```
PATH=/home/user1/hadoop/bin:/home/user1/hadoop/sbin:$PATH
export PATH
```

Then to update your current running shell with the new value, do the following:

`$ source .bashrc`

To validate, just type `hdfs` with double tabs. Do you see anything?

HDFS Configuration

Now let us move on to configuring Hadoop.

19. Open the `/home/user1/hadoop/etc/hadoop/core-site.xml` file and add the lines below. Don't forget to change the name of the host to `nnode.yourname.local`.

```
<configuration>
  <property>
    <name>fs.defaultFS</name>
    <value>hdfs://nnode.ali.local:9000</value>
  </property>
  <property>
    <name>hadoop.tmp.dir</name>
    <value>/home/user1/hadoop/tempdata</value>
  </property>
</configuration>
```

20. Create the `tempdata` directory inside the `hadoop` directory.
21. Now open the `/home/user1/hadoop/etc/hadoop/hdfs-site.xml` file and make sure you have your settings similar to the following:

```
<configuration>
  <property>
    <name>dfs.replication</name>
    <value>2</value>
    <name>dfs.name.dir</name>
    <value>file:///home/user1/hadoop/hdfs/namenode</value>
    <name>dfs.data.dir</name>
    <value>file:///home/user1/hadoop/hdfs/datanode</value>
    <name>dfs.namenode.num.checkpoints.retained</name>
    <description>No. of edits/fsimages to retain</description>
    <value>10</value>
  </property>
</configuration>
```

Create both of those directories:

```
$ mkdir -p hadoop/hdfs/{namenode,datanode}
```

22. Finally, open the `hadoop/etc/hadoop/workers` file and make sure you add your datanodes there, like this:

```
dnnode1.ali.local
dnnode2.ali.local
```

23. Adding the location of JAVA to your `hadoop-env.sh` file, so hadoop know where to look for JAVA. This could be done by opening the `/home/user1/hadoop/etc/hadoop/hadoop-env.sh` file and adding the line under the line “# export JAVA_HOME=”
`export JAVA_HOME=/usr/lib/jvm/java-8-openjdk-amd64`

Before we move on to starting our hadoop cluster, we need to copy all of the files to the datanodes we have. We can simply do that using scp.\

24. Now, copy the files from your name node to the datanodes using the command below. Don't forget to adjust your command to your hostname.
`$ scp -r hadoop user1@dnnode1.ali.local`

Do the same for the other datanodes.

Starting our Hadoop Cluster

Now it is time to start our hadoop cluster for the first time. But, before we do that, we need to format the cluster.

25. To format our hadoop cluster, on the namenode, do the following:

```
$ hdfs namenode -format
```

```
user1@nnode:~$ hdfs namenode -format
2019-04-10 07:01:17,879 INFO namenode.NameNode: STARTUP_MSG:
/*****
STARTUP_MSG: Starting NameNode
STARTUP_MSG:  host = nnode.ali.local/172.16.150.10
STARTUP_MSG:  args = [-format]
STARTUP_MSG:  version = 3.1.2
```

And:

```
2019-04-10 07:01:29,063 INFO namenode.NameNode: SHUTDOWN_MSG:
/*****
SHUTDOWN_MSG: Shutting down NameNode at nnode.ali.local/172.16.150.10
/*****
```

26. Check the hadoop version, similar to the screenshot below.

```
$ hadoop version
```

Or use the `hdfs` command instead, both should work.

27. Now to start your cluster, use the `start-dfs.sh` command.

28. Now run the `jps` command to check the status.

29. Go to your datanode (any of them) and run the `jps` command.

```
user1@nnode:~$ start-dfs.sh
Starting namenodes on [nnode.ali.local]
Starting datanodes
Starting secondary namenodes [nnode.ali.local]
user1@nnode:~$ jps
5650 SecondaryNameNode
5363 NameNode
5764 Jps
user1@nnode:~$ █
```

On datanode1:

```
user1@dnode1:~$ jps
3081 Jps
3019 DataNode
```

30. Run a report check on the namenode using:

```
$ hdfs dfsadmin -report
```

```
Configured Capacity: 84008173568 (78.24 GB)

```

31. Let us test the cluster by creating a for420 directory. This could be done using the command below.

```
$ hdfs dfs -mkdir /for420
```

32. Let us check if the directory was created using the dfs **ls** command as seen below.

```
$ hdfs dfs -ls /
```

33. You will see results similar to the screenshot below.

```
user1@node:~$ hdfs dfs -ls /  
Found 1 items  
drwxr-xr-x  - user1 supergroup          0 2019-04-10 07:30 /for420
```

Accessing the Web Interface

We have configured hadoop to also be accessed by the web interface. Check it out.

34. On your system with your browser, go to the IP Address (or hostname if your system is configured properly) and navigate to the following:

<http://172.16.150.10:9870/>

35. You should receive an overview page, similar to the one below.

Overview 'nnode.ali.local:9000' (active)

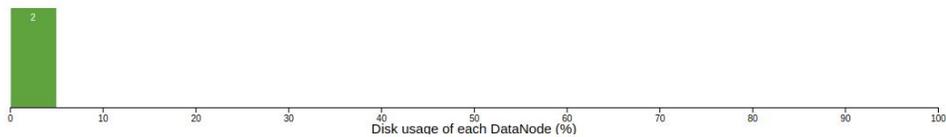

Started:	Wed Apr 10 03:22:15 -0400 2019
Version:	3.1.2, r1019dde65bcf12e05ef48ac71e84550d589e5d9a
Compiled:	Mon Jan 28 20:39:00 -0500 2019 by sunilg from branch-3.1.2
Cluster ID:	CID-3f6d70a8-89d8-42a2-8e85-a371fd038a21
Block Pool ID:	BP-519778240-172.16.150.10-1554879688845

36. Go to the Datanodes tab and check that your datanodes are there.
