ABSTRACT

Weakly-supervised semantic segmentation (WSSS) is introduced to narrow the gap for semantic segmentation performance from pixel-level supervision to image-level supervision. Most advanced approaches are based on class activation maps (CAMs) to generate pseudo-labels to train the segmentation network. The main limitation of WSSS is that the process of generating pseudo-labels from CAMs which use an image classifier is mainly focused on the most discriminative parts of the objects. To address this issue, we propose Puzzle-CAM, a process minimizes the differences between the features from separate patches and the whole image. Our method consists of a puzzle module (PM) and two regularization terms to discover the most integrated region of in an object. Without requiring extra parameters, Puzzle-CAM can activate the overall region of an object using image-level supervision. In experiments, Puzzle-CAM outperformed previous state-of-the-art methods using the same labels for supervision on the PASCAL VOC 2012 test dataset. Code associated with our experiments is available at https://github.com/OFRIN/PuzzleCAM.

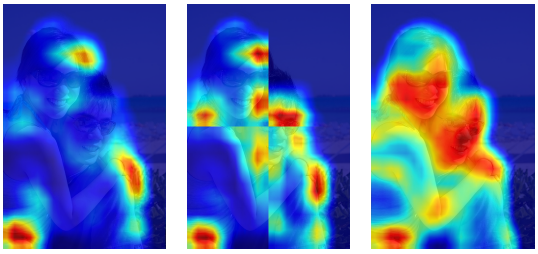
1. INTRODUCTION

Semantic segmentation is a fundamental approach using convolutional neural networks (CNNs) with the aim of correctly predicting the pixel-wise classification of an image. Recently, fully-supervised semantic segmentation (FSSS) has achieved remarkable progress [1, 2, 3]. However, producing large-scale training datasets with precise pixel-level annotations per image is considerably expensive and requires labor-intensive and time-consuming tasks. To solve this issue, many researchers have focused on weakly supervised semantic segmentation (WSSS), which is used to train networks using image-level annotations, scribbles, bounding boxes, and points. Image-level supervision can be more easily conducted than other approaches in a group of weak supervision processes. In this study, we only focused on learning semantic segmentation models using image-level supervision.



(a) (b) (c)

Fig. 1: A comparisons of CAMs generated from tiled and original image: (a) conventional CAMs from the original image, (b) generated CAMs from the tiled images, and (c) predicted CAMs by the proposed Puzzle-CAM.

Most previous methods [4, 5, 6] using WSSS are based on the class activation maps (CAMs) [7] to achieve good performance. However, the generated CAMs are usually focused on small parts of the semantic objects to efficiently classify them, which prevents the segmentation models from learning pixel-level semantic knowledge. Moreover, we can see that the CAMs generated from isolated patches in the tiled image are no different those gained from the original image. As shown in Fig. 1, CAMs of the tiled image comprising tiled patches are significantly inconsistent compare to those of the original image. The differences are factored in enlarging the supervision gap between FSSS and WSSS by even more.

The above observations gave us the inspiration to address WSSS issues by using an attention-based feature learning method. To detect integrated regions of objects, we propose Puzzle-CAM for WSSS training. Our method applies consistency regularization that corresponds to the generated CAMs from the tiled and original images to provide self-supervision. To improve the network prediction consistency further, we introduce a puzzle-module (PM) that splits the image and merges CAMs generated from the tiled image. Puzzle-CAM consists of a Siamese neural network with reconstructing regularization loss that reduces the differences between the original and merged CAMs. Our experiments yielded both

quantitative and qualitative results that demonstrate the superiority of our approach.

Our main contributions are as follows:

- We propose Puzzle-CAM that incorporates reconstructing regularization with a puzzle module (PM), to effectively enhance the quality of CAMs without adding layers.
- Puzzle-CAM outperformed existing state-of-the-art methods with the same level of supervision on the PASCAL VOC 2012 dataset.

2. RELATED WORK

In this section, we introduce some works, including attention mechanisms using CNNs and WSSS, both of which are components of Puzzle-CAM.

2.1. Attention Mechanisms Using CNNs

These provides a fine-grained information on the features learned in CNNs. Simonyan *et al.* [8] used the error back-propagation strategy to visualize semantic regions whereas the combined attention model used the global average pooling (GAP) layer in CNNs to generate the CAMs [7] more efficiently. Last, a final classifier is used to generate attention maps. To the best of our knowledge, which attention mechanism is chosen does not have a great effect on achieving high performance with WSSS, and so we based Puzzle-CAM on the combined attention model because it is more manageable than the other attention mechanism.

2.2. Weakly Supervised Semantic Segmentation

Unlike FSSS, which requires a pixel-wise labels for an image, WSSS employs lower level labeling, such as bounding boxes [9], scribbles [10], and image-level classification labels [4, 6]. Recently, the performance of WSSS has been significantly boosted by incorporating the CAMs. Most of previous WSSS methods refine the CAMs generated by the image classifier to approximate the segmentation mask [4, 11, 12, 13, 6]. AffinityNet [4] trains an additional network to learn similarities between the pixels, which often generates a transition matrix and multiplies with CAM to adjust its activation coverage. IRNet [11] generates a transition matrix from the boundary activation map and extends the method to achieve weakly supervised instance segmentation (WSOS) and WSSS. SEAM [5] aims to refine class activation maps using a pixel correlation module that captures context appearance information for each pixel and alters the original CAMs by using learned affinity attention maps.

3. METHODOLOGY

3.1. Motivation

Most WSSS approaches are based on CAMs to obtain a segmentation mask using image-level supervision. Usually, the CAMs are focused on the discriminative region of object. The well-known reason is that a normal image classifier only uses the classification loss, which induces a partial region to be activated in objects during training. The CAMs generated from a tiled image causes over-activation since the image does not have global-context information. To address this issue, we propose Puzzle-CAM improves network for consistent prediction matching partial and full features. Puzzle-CAM contains designed loss functions to match the CAMs generated from a tiled image with the original image (see Fig. 2).

3.2. The Employed CAM Method

We first introduce the CAM method for producing the initial attention map. Given the feature extractor F, and classifier θ, we generate CAMs A which is the collection of CAM for entire classes. After training the classifier by image-level supervision, we apply the weights of the c-channel classifier as θ^c on the feature map $f = F(I)$ from an input Image I to obtain CAM of class c as follows:

$$A_c = \theta_c^\top f. \tag{1}$$

The generated CAM is normalized by using the maximum value of A_c. Finally, we obtain the CAMs for entire classes A by concatenating A_c from every class.

3.3. The Puzzle Module

When matching partial and full features, the key is to narrow the gap between FSSS and WSSS. The puzzle module consists of tiling and merging modules. From an input image I of size $W \times H$, the tiling module generated a tiled, non-overlapping images $\{I^{1,1}, I^{1,2}, I^{2,1}, I^{2,2}\}$ size of $W/2 \times H/2$. For each $I^{i,j}$, we generate CAMs $A^{i,j}$. Finally, the merging module attaches all $A^{i,j}$ into a single CAMs A^{re} that has the same shape as the CAMs of I, A^s.

3.4. Loss Design of Puzzle-CAM

We employed a GAP layer at the end of the network to incorporate prediction vector $\hat{Y} = \sigma(G(A_c))$ for image classification and to adopt multi-label soft margin loss for the classification task. For notational convenience, we define Y_t as

$$\hat{Y}_t = \begin{cases} \hat{Y}, & \text{if } Y = 1 \\ 1 - \hat{Y}, & \text{otherwise} \end{cases} \tag{2}$$

$$\ell_{cls}(\hat{Y}, Y) = -log(Y_t). \tag{3}$$

The CAMs of the original (A^s) and tiled images (A^{re}) converted using the GAP layer as prediction vectors $\hat{Y}^s = G(A^s)$ and $\hat{Y}^{re} = G(A^{re})$, respectively. The classification losses for the original and reconstructed images are respectively calculated as follows:

$$\mathcal{L}_{cls} = \ell_{cls}(\hat{Y}^s, Y), \tag{4}$$

$$\mathcal{L}_{p-cls} = \ell_{cls}(\hat{Y}^{re}, Y). \tag{5}$$

These two classification losses are used to improve the performance of the image classification. To reinforce the CAMs from the original image, we added reconstructing regularization to correspond with the original and reconstructed CAMs. The reconstruction loss for the original CAM can be easily defined as:

Table 1: Ablation study for each loss function consisting of Puzzle-CAM using ResNet-50 as their backbone.

L_{cls}	L_{p-cls}	L_{re}	mIoU (%)
✓			47.82
✓	✓		47.70
✓		✓	49.21
✓	✓	✓	**51.53**

$$\mathcal{L}_{re} = \left\| A^s - A^{re} \right\|_1. \tag{6}$$

In summary, the final loss of Puzzle-CAM is defined as:

$$\mathcal{L} = \mathcal{L}_{cls} + \mathcal{L}_{p-cls} + \alpha \mathcal{L}_{re}. \tag{7}$$

where α is the balance of the weights for the different losses. The classification losses, $\mathcal{L}_{cls}$ and $\mathcal{L}_{p-cls}$, are used to roughly estimate the region of the object. The reconstruction loss, $\mathcal{L}_{re}$, is used to narrow the gaps between the pixel- and image-level supervision processes. We report details of the network training settings and probe into the effectiveness of the proposed module in the experiments section.

4. EXPERIMENTAL RESULTS

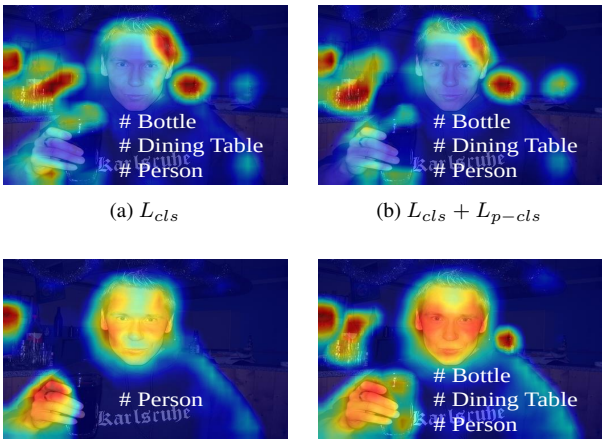
4.1. Implementation Details

We evaluated our method using the PASCAL VOC 2012 dataset [14]. The dataset is separated into 1,464 images for training, 1,449 for validation, and 1,456 for testing. Following the experimental protocol used in previous methods, we took additional annotations from the Semantic Boundary Dataset [15] to build an augmented training set with 10,582 images. The images were randomly re-scaled in the range of [320, 640] and then cropped by 512×512 as the network inputs. For all experiments, we set maximum $\alpha = 4$ and linearly ramped up α to its maximum value until a half epochs. During inference, we utilized classifiers without the puzzle module. Thus, we adopted multi-scale and horizontal flip to generate pseudo-segmentation labels. We made the model train the dataset on four TITAN-RTX GPUs.

4.2. Ablation Studies

We conducted ablation studies on the main components of Puzzle-CAM under the mIoU metric (see Table 1), for which its baseline achieved $mIoU = 47.82\%$. With the proposed reconstructing regularization $\mathcal{L}_{re}$ of the tiled patches, the baseline was boosted to $mIoU = 49.21\%$, while the proposed classification loss from the tiled patches $\mathcal{L}_{p-cls}$ is similar to the baseline. Both the $\mathcal{L}_{re}$ and the $\mathcal{L}_{p-cls}$ consistently improved the baseline by a 3.71% gain.

We visualized the CAMs according to using combinations of loss functions individually (see 3). If the classification losses are only employed (L_{p-cls}), the result shows no



(a) L_{cls} (b) $L_{cls} + L_{p-cls}$

(c) $L_{cls} + L_{re}$ (d) $L_{cls} + L_{p-cls} + L_{re}$

Fig. 3: The visualization of the predicted tags and CAMs by using combinations of loss functions. The final CAMs (d) not only suppresses over-activation but also expands CAMs into complete object activation coverage .

Table 2: Quality of the pseudo semantic segmentation labels in mIoU, evaluated on the PASCAL VOC 2012 training set [14]. RW: random walk with AffinityNet [4], dCRF: dense conditional random field [16].

Method	Backbone	CAM (%)	CAM +RW (%)	CAM+RW +dCRF (%)
AffinityNet [4]	ResNet-50	47.82	58.10	59.70
Puzzle-CAM	ResNet-50	51.53	64.16	64.70
Puzzle-CAM	ResNeSt-50	57.59	69.48	69.91
Puzzle-CAM	ResNeSt-101	61.85	71.92	72.46
Puzzle-CAM	ResNeSt-269	**62.45**	**74.14**	**74.67**

marginal difference. Meanwhile, if the reconstruction loss is only employed (L_{re}), the result shows the improved localization ability for some class than the original, but it failed to predict several classes. When the entire losses are combined, the result shows the improved localization without suffering the classification.

4.3. Comparisons with Existing State-of-the-art methods

To further improve the accuracy of pseudo pixel-level annotations, we followed the approach in [4] to train AffinityNet based on Puzzle-CAM. We adopted ResNeSt architecture that universally improves the learned feature representations to boost performance across image classification, object detection, instance segmentation and semantic segmentation. In Table 2, we report the performances with the original CAMs used by the baseline AffinityNet [4] and Puzzle-CAM.

The final synthesized pseudo-labels achieved 74.67% mIoU on the PASCAL VOC 2012 *train* set. Puzzle-CAM was then used to train the segmentation model DeepLabv3+ [1] with the ResNeSt-269 [18] backbone using the pseudo-labels in full supervision to achieve the final segmentation

Table 3: Comparison of Puzzle-CAM and existing state-of-the-art methods on the PASCAL VOC 2012 dataset. $\mathcal{I}$, image-level labels; $\mathcal{S}$ external saliency models.

Method	Backbone	Sup	val	test
AffinityNet [4]	Wide-ResNet-38	$\mathcal{I}$	61.7	63.7
DSRG [12]	ResNet-101	$\mathcal{I}+\mathcal{S}$	61.4	63.2
SeeNet [13]	ResNet-101	$\mathcal{I}+\mathcal{S}$	63.1	62.8

results. Table 3 reports a comparison of the mIoU for proposed method and the previous approaches. Compared to the baseline methods, Puzzle-CAM had remarkably improved performances on both val and $test$ sets with the same settings for training. Fig. 2 shows some qualitative results on $test$ set, which illustrates that the proposed method worked well on both large and small objects.

5. CONCLUSIONS

In this paper, we proposed the Puzzle-CAM algorithm to narrow the supervision gaps between FSSS and WSSS using image-level labels. To improve the network for generating consistent CAM, we designed a puzzle module and adopted reconstructing regularization to match partial and full features. Not only did Puzzle-CAM consistently generate features from local tiled patches but it also fitted the shape of the ground truth masks better. The segmentation network trained by our synthesized pixel-level pseudo-labels achieved state-of-the-art performance on the PASCAL VOC 2012 dataset, which proves the effectiveness of our approach. We believe that the concepts of Puzzle-CAM as a training module can be generalized and will benefit other weakly- and semi-supervised tasks, such as semantic and instance segmentation.
